ABSTRACT: A safer treatment for toxoplasmosis would be achieved by improving the selectivity and potency of dihydrofolate reductase (DHFR) inhibitors, such as pyrimethamine (1), for Toxoplasma gondii DHFR (TgDHFR) relative to human DHFR (hDHFR). We previously reported on the identification of meta-biphenyl analog 2, designed by in silico modeling of key differences in the binding pocket between TgDHFR and hDHFR. Compound 2 improves TgDHFR selectivity 6.6-fold and potency 16-fold relative to 1. Here, we report on the optimization and structure–activity relationships of this arylpiperazine series leading to the discovery of 5-(4-(3-(2-methoxypyrimidin-5-yl)phenyl)piperazin-1-yl)pyrimidine-2,4-diamine 3. Compound 3 has a TgDHFR IC_{50} of 1.57 ± 0.11 nM and a hDHFR to TgDHFR selectivity ratio of 196, making it 89-fold more potent and 16-fold more selective than 1. Compound 3 was highly effective in control of acute infection by highly virulent strains of T. gondii in the murine model, and it possesses the best combination of selectivity, potency, and prerequisite drug-like properties to advance into IND-enabling, preclinical development.

INTRODUCTION

Toxoplasmosis is caused by the protozoan parasite Toxoplasma gondii (T. gondii), an obligate intracellular parasite capable of infecting a wide range of hosts and many different types of cells.1 Approximately one-third of the population worldwide is chronically infected with various strains of T. gondii.2 Infections occur through consuming contaminated food or water and mother-to-child (congenital/vertical) and iatrogenic (transplanted organs and blood transfusion) transmission.3 The parasitic infection is kept in check by the immune system where it exists in a latent bradyzoite form contained within tissue cysts that are commonly found in skeletal muscle and the central nervous system (CNS).4 However, in cases where the immune system is compromised, such as in a developing fetus or in patients with HIV, undergoing cancer chemotherapy or immunosuppressive treatment for organ transplantation, the parasite can transition to an active, fast replicating, and tissue damaging tachyzoite form.5 Depending upon localization of the tachyzoites, active infection can cause, among other conditions, myocarditis, blindness, and encephalitis and is associated with a high mortality rate for HIV patients, even for those on active antiretroviral treatment.6–8

The recommended first-line treatment for toxoplasmosis is a combination therapy based on pyrimethamine (1) and sulfadiazine, supplemented with leucovorin (also known as folinic acid) to protect against bone marrow suppression.9 Pyrimethamine and sulfadiazine act synergistically on the folate metabolic pathway thereby inhibiting T. gondii proliferation and survival.9,10 The drugs inhibit DHFR and dihydropteroate synthase (DHPS), respectively, and consequently block the synthesis of tetrahydrofolate, a key cofactor for thymidylate synthase. Thymidylate synthase is a methyl transferase that produces deoxythymidine monophosphate from deoxyuridine monophosphate. In many organisms including T. gondii and humans, this pathway is the only means by which thymidine can be supplied, making it essential for DNA synthesis and cellular proliferation.10,11 Importantly, although the combination of pyrimethamine and sulfadiazine can control actively proliferating forms such as tachyzoites, these agents have little effect on the semidormant bradyzoite stages within tissue cysts and hence do not cure infection.12

Adverse events associated with pyrimethamine-based therapy in toxoplasmosis often result in a need to reduce dosing or discontinue therapy. The adverse events are mainly mechanism-based related to inhibition of folic acid metabolism in host tissues with high metabolic activity (e.g., epithelium and bone marrow). In mice, pyrimethamine has only about a 3-fold safety multiple between minimal effective dose and maximum tolerated dose. Leucovorin, a form of tetrahydrofolate that is selectively taken up by human cells, is often coadministered to help alleviate the impact of mechanism-based toxicity to the host.

The use of pyrimethamine is also not suitable during the first trimester of pregnancy owing to its inhibition of human DHFR which can impact fetal organogenesis. In addition, about 3% of the general population and 30% of patients with HIV/AIDS have a hypersensitivity reaction to the sulfonamide component of the treatment regimen. Therefore, finding a standalone treatment would be of significant benefit to the HIV patient population most at risk of toxoplasmosis encephalitis and sulfonamide hypersensitivities. Finally, high doses of pyrimethamine can induce seizures, a likely consequence of off-target pharmacology. The adverse events associated with pyrimethamine and sulfadiazine therapy could be reduced or eliminated by selectively inhibiting only the parasite DHFR. There have been numerous attempts to discover more selective inhibitors of TgDHFR but with limited success. Recently, the crystal structure of TgDHFR was solved. This finding has enabled comparative modeling between the human and T. gondii enzymes, leading to the design and discovery of more selective TgDHFR small molecules such as TRC-19.

Ideally, a next generation TgDHFR inhibitor would have sufficient selectivity so that maximal parasiticidal activity would occur without concomitant inhibition of human hDHFR. Therefore, we hypothesized it would be important that the compound exhibit TgDHFR to hDHFR selectivity of at least 150-fold, which is about 10-fold greater than that of pyrimethamine, and possess low clearance to minimize maximal plasma concentrations while achieving a long duration of maximally effective exposure. Given the ability of parasites to invade the CNS, it is also necessary that the compound readily penetrate the blood–brain barrier. Finally, improving TgDHFR potency can reduce effective dose levels and decrease the likelihood of compound related off-target pharmacology and associated side effects and toxicity.

In this study, we report on the SAR and lead optimization strategy underlying the discovery of 5-(4-(3-(2-methoxypyrimidin-5-yl)phenyl)piperazin-1-yl)pyrimidine-2,4-diamine, a selective and potent TgDHFR inhibitor with properties consistent with those outlined above supporting the first standalone treatment for toxoplasmosis.

## RESULTS AND DISCUSSION

### Pyrimethamine Selectivity and Potency

Pyrimethamine 1 is reported to be 7.6-fold more selective for TgDHFR compared to hDHFR with a hDHFR IC_{50} of 760 ± 130 nM for inhibiting conversion of dihydrofolate to tetrahydrofolate. More recently, the K_{i} for hDHFR was reported to be 470 nM. In our hands, 1 has an IC_{50} for inhibiting TgDHFR of 139 ± 49 nM (Figure 1), which makes it 12-fold more potent for inhibiting TgDHFR over hDHFR. Although this level of selectivity is sufficient to make 1 a preferred DHFR inhibitor for the treatment of toxoplasmosis, as can be seen in Figure 1, it is not sufficient to preclude inhibition of hDHFR and associated dose limiting mechanism-based toxicity. The concentration of 1 that gives significant inhibition of TgDHFR, i.e., > IC_{50} begins to also inhibit hDHFR by 5–35%. On the basis of these data, it seemed reasonable that at least an order of magnitude and preferably 20-fold increase in selectivity in a new compound would be sufficient to overcome the mechanism-based toxicity issues observed with 1 and possibly enable a standalone therapy.

### Early Profiling Data for Lead 2 and Comparison to DHFR Inhibitor Reference Standard Drugs

The structures of lead 2 and DHFR inhibitor reference compounds pyrimethamine (1), trimethoprim (4), methotrexate (5), and trimetrexate (6) are shown in Figure 2. The DHFR inhibitory activity and selectivity, kinetic solubility, human liver microsomal intrinsic clearance, and permeability and efflux across an MDR1-MDCK cell monolayer for lead 2 and reference compounds 1, 4, 5, and 6 are shown in Table 1. Lead 2 has a TgDHFR IC_{50} of 8.76 ± 1.0 nM with 79-fold selectivity relative to the human enzyme. This is 6.6-fold more selective than 1. Although this improvement in selectivity was encouraging, in our view is insufficient to achieve a stand-alone treatment. Trimethoprim 4, sometimes used off label in combination with sulfamethoxazole for the treatment of toxoplasmosis, was about 240-fold less potent against TgDHFR than 1 with an IC_{50} of 33 100 nM and selectivity index of 15. Methotrexate 5 was far more potent than 1, 4, or 2 for inhibiting hDHFR with an IC_{50} of 4.74 nM. Interestingly, 5 has the opposite selectivity profile as compared to 1, where it is 17-fold less potent for inhibiting TgDHFR (IC_{50} of 78.3 nM), giving a selectivity ratio of 0.061. Trimetrexate 6, which structurally is a combination of the diaminopteridine head of 5 and trimethoxybenzyl tail of 4, is nearly equally active at TgDHFR and hDHFR with respective IC_{50}’s of 1.35 and 4.07 nM, giving a selectivity index of 3.0.

Further characterization of 1 and 2 was performed to benchmark and guide a lead optimization strategy (Table 1). Lead 2 has low kinetic and thermodynamic solubility (<4 μM), high clearance in human liver microsomes (HLM) (i.e., > liver blood flow), and low to moderate MDCK-MDR1 permeability, all areas for improvement during lead optimization. Interestingly, 1, which was discovered and developed in the 1940s, has near ideal CNS drug properties in terms of solubility, HLM stability, and MDR1-MDCK permeability. Properties for 1 and 2 are summarized in Table 2, with the main differences being an increase in both MW and log P for 2, which likely contributes to its undesirable solubility, metabolic stability, and permeability profile. On the basis of these data, lead
optimization was initially focused on understanding the SAR underlying selectivity and potency while simultaneously designing analogs with lower cLogP and higher calculated solubility in an effort to improve physical chemical properties.

Structure–Activity Relationships for Analogos of 2. Structure–activity relationship (SAR) data based on 2 for inhibition of TgDHFR and selectivity relative to hDHFR are shown in Tables 3–5. Initial optimization of 2 focused on a systematic approach to gain a better understanding of its SAR with emphasis on improving DHFR selectivity (Table 3). As a basis for comparison, unsubstituted analog 7 was prepared and found to lose potency (IC$_{50}$ = 209 nM) but maintained a similar selectivity index (59-fold) relative to initial lead 2. Ortho-phenyl 8 and para-phenyl 9 were both about 4-fold less potent (IC$_{50}$ ∼ 30 nM) than 2 but differed in their selectivity profiles. Ortho-phenyl 8 maintained similar selectivity as 2 at 58-fold, whereas para-phenyl 9 had reduced selectivity at 11-fold. These data are consistent with modeling predictions of the binding cavity. 30 Replacing the distal meta-phenyl of 2 with an ortho-methyl 10 or ortho-chloro 13 resulted in complete loss of activity at the highest doses tested. This result is surprising considering ortho-phenyl analog 8 had a TgDHFR IC$_{50}$ of 31 nM. Meta-methyl and meta-chloro analogs 11 and 14 respectively were more potent and selective than corresponding para-substituted compounds 12 and 15, supporting the hypothesis based on modeling that meta-substituents would be preferred. Encouragingly, meta-methyl 11, while 8-fold less potent than 2, maintained equivalent selectivity of 79-fold. On the basis of these findings, design focused on meta-substituents to further probe this apparently important pocket for both selectivity and potency. Meta-methoxy 16, meta-trifluoromethyl 17, meta-trifluoromethoxy 18, and meta-cyclopropyl 19 all had reduced potency and selectivity as compared to meta-phenyl lead 2. Adding a methyl or ethyl to the 6-position of the diaminopyrimidine group, giving 20 and 21 respectively, maintained or slightly improved potency over 2 but with a slight loss in selectivity.

Structure–Activity Relationships for Heteroaryl Analogos of Meta-Biphenyl 2. We then turned our focus toward improving the solubility and metabolic stability issues observed with early lead 2 by preparing a variety of heteroaryl analogs (Table 4). We hypothesized that the distal phenyl ring of 2 was the likely site of metabolism and that introducing nitrogen molecules into this ring would block metabolism and increase solubility. The 2-, 3-, and 4-pyridine analogs 22, 23, and 24 maintained or slightly improved potency and selectivity but without much improvement in solubility. The potency of 3-pyridine analog 23 is noteworthy at 2.7 nM, about 3.3-fold more potent than 2, and with a selectivity index of 112-fold. Addition of a second nitrogen into this ring would block metabolism and increase solubility. The 2-, 3- and 4-pyridine analogs 22, 23, and 24 maintained or slightly improved potency over 2 but with a slight loss in selectivity.

Next, we evaluated if selectivity could be further improved by adding substitutions onto the 2-position of the distal 5-pyrimidine ring (Table 5). On the basis of the crystal structure and modeling (see Figures 3 and 4), it appeared that substitutions onto the 2-position of the distal 5-pyrimidine ring evaluated if selectivity could be further improved by adding substitutions onto the 2-position of the distal 5-pyrimidine ring (Table 5). On the basis of the crystal structure and modeling (see Figures 3 and 4), it appeared that substitutions onto the 2-position of the distal 5-pyrimidine ring evaluated if selectivity could be further improved by adding substitutions onto the 2-position of the distal 5-pyrimidine ring (Table 5). On the basis of the crystal structure and modeling (see Figures 3 and 4), it appeared that substitutions onto the 2-position of the distal 5-pyrimidine ring evaluated if selectivity could be further improved by adding substitutions onto the 2-position of the distal 5-pyrimidine ring.

with a 307-fold TgDHFR selectivity index and a TgDHFR IC₅₀ of 5.2 nM, as well as markedly improved solubility (>200 μM) and metabolic stability (Clint < 8.6 mL min⁻¹ kg⁻¹). The improvement in selectivity observed for 26 is nearly 4 times that of early lead 2 and 25-fold better than 1. 2-Pyrazine 27 and 4-pyridazine 28 had promising potency with IC₅₀ values of 10 and 6.0 nM, respectively, and selectivity indexes of 129 and 185-fold, respectively, but both were hampered with low kinetic solubility, precluding additional investigation with these chemotypes. In general, heteroaryl substitutions increase TgDHFR selectivity and maintain or slightly improve potency relative to 2. The 2-fold improvement in selectivity observed for 5-pyrimidine analog 26 compared to the 3-pyridyl analog 23 may result from one of the nitrogen atoms on the distal pyrimidine ring being forced to make an unfavorable interaction in hDHFR. The 3-pyridyl analog 23, which can rotate the nitrogen away from such an unfavorable interaction, is about 5-fold more potent at hDHFR than pyrimidine 26 (hDHFR IC₅₀ = 1430 nM).

**SAR for the Distal 5-Pyrimidine Ring of 26.** Next, we evaluated if selectivity could be further improved by adding substitutions onto the 2-position of the distal 5-pyrimidine ring of 26 (Table 5). On the basis of the crystal structure and modeling (see Figures 3 and 4), it appeared that substitutions at this position were not likely to have steric effects as they pointed into solvent space. However, if the pyrimidine nitrogen atoms were making a favorable hydrogen bond interaction with TgDHFR His-27 and an unfavorable interaction with hDHFR Pro-26, then electron donating substituents would be predicted to enhance potency and

**Figure 3.** Crystal structure of TgDHFR with pyrimidine 29 bound. Crystal structure data were visualized and modeled using MOE software from Chemical Consulting Group.

**Figure 4.** Crystal structure of TgDHFR with pyrimidine 3 bound. Crystal structure data were visualized and modeled using MOE software from Chemical Consulting Group.

selectivity. Methyl analog 29 maintained TgDHFR potency (IC₅₀ = 3.95 nM) with only a slight reduction in selectivity (237-fold) relative to unsubstituted 5-pyrimidine 26. Methyl analog 29 had good solubility, HLM stability, and MDCK-MDR1 permeability. An electron donating 2-methoxy substituent gave 3, with excellent TgDHFR potency with an IC₅₀ of 1.57 nM but a slightly reduced selectivity index of 196. Trifluoromethyl 30 and cyclopropyl 31 were significantly less potent against TgDHFR, less selective and had lower kinetic solubility. The loss in selectivity with these analogs is principally driven more by loss of activity against TgDHFR rather than by gaining potency at hDHFR.

Further characterization of 3 demonstrated good kinetic solubility of 186 μM at pH 7.4, low human microsomal clearance (<8.6 mL min⁻¹ kg⁻¹), and high permeability in MDR1-MDCK cells (20.1 × 10⁻⁶ cm/s) with a lower efflux ratio of 1.1 (Table 5). In the CEREP 44 safety screen at a 10 μM dose level, 3 demonstrated good selectivity against all 44 targets tested except for hERG where [³H]dofetilide binding was inhibited by 60%.

**Chemistry.** The compounds presented here were synthesized as shown in Schemes 1 and 2. In Scheme 1, substituted piperazines (36a–n) were condensed with 5-bromouracil 33 in the presence of KF and heating in DMSO to give the corresponding uracil derivatives 37a–n. Chlorination using POCl₃ and DIPEA provided intermediates 38a–n, followed by amination reaction using NH₃/EtOH at 145 °C to give final products 2, 7–18, 20, 21, and 32. 6-Methyl and 6-ethyl diaminoypyrimidine targets 20 and 21 were synthesized as described above but starting with the corresponding 6-alkyl-5-bromouracils 34 and 35 and condensing with biphenylpiperazine 36a. Piperazine intermediates 36a–n are generally commercially available or can be prepared by various literature methods.³⁴–³⁵

Analogs in Scheme 2 were prepared by either Suzuki coupling of 3-bromophenyl 32 with the corresponding boronic acids 39o–w to give targets 3, 19, 23, 24, 26, and 28–31 or Stille coupling of 3-bromophenyl 32 with Sn(Bu)₃ to generate compounds 22, 25, and 27.

**Crystal Structure of TgDHFR.** To aide in the understanding of the observed selectivity and guide future lead optimization efforts, several X-ray crystal structures with lead compounds bound to TgDHFR were solved, including the complex of 5-pyrimidines 3 and 29 with TgDHFR (Figures 3 and 4). Although at a high-level these data are consistent with modeling predictions, the crystal structure provides more subtle clues into why the distal pyrimidine moiety enhances selectivity. The phenyl groups of 3 and 29 occupy the...
parasiticidal activity with similar efficacy as 1, but with substantially better potency and selectivity (Figure 5).

Comparison of Potency against Additional Strains of Toxoplasma. Given the enhanced potency of 3, we wanted to test it against different lineages of T. gondii. Consequently, we chose a series of low passage isolates that are representative of the major genotypes of T. gondii seen in human infection from different regions of the world. As we have previously described, the population structure of T. gondii comprises six major morphisms related to these amino acids that would alter selectivity.37

Parasiticidal and Antiproliferative Effects of 5-Methoxypyrimidine 3 in Cell-Based Models. Optimized pyrimidine 3 and comparator drug 1 were evaluated in cell-based models to investigate translation of the respective DHFR inhibitory activities into parasiticidal and antiproliferative host cell effects. Lead 3 had a parasiticidal EC$_{50}$ of 13 nM and 1 had an EC$_{50}$ of 680 nM against the type 1 RH strain of T. gondii. The S2-fold improvement in potency of 3 over 1 in this assay is consistent with its 89-fold potency advantage for inhibiting TgDHFR. Antiproliferative effects of these compounds in human MCF-7 cells, measured using the MTT assay, were consistent with the human DHFR data, wherein 1 and 3 had EC$_{50}$ values of 11 600 nM and 7300 nM, respectively. The selectivity of both 1 (17-fold) and 3 (560-fold) in the cell-based assays (Table 6) is in line with their DHFR selectivity profiles of 12- and 200-fold, respectively. These data are important as they demonstrate that 3 has antiparasiticidal activity with similar efficacy as 1, but with substantially better potency and selectivity (Figure 5).

Reagents and conditions: (a) Pd(PPh$_3$)$_4$, R$_2$ 2-B(OH)$_2$ (cyclopropylpyrimidine), (x) 2-pyridine, (y) 2-pyrimidine and (z) 2-methylpyrimidine, (v) 5-(2-trifluoromethylpyrimidine), (w) 5-(2-cyclopentylpyrimidine), (x) 2-pyridine, (y) 2-pyrimidine and (z) 2-pyrazine. Reagents and conditions: (a) Pd(PPh$_3$)$_4$, R$_2$ 2-B(OH)$_2$ (390–w), Cs$_2$CO$_3$, dioxane/H$_2$O, 110 °C; or (b) Pd$_2$(dba)$_3$, Sn(nBu)$_3$-R$_2$ (40x–z), XPhos, dioxane, 100 °C.

TgDHFR cavity created near F91 and G22 (Figure 4), while the residues present in hDHFR at these positions appear to be less accommodating. These TgDHFR phenylalanine residues (F32 and F91) create a more enclosed hydrophobic area around the phenyl ring connected to the piperazine. This configuration also positions the distal heteroaromatic ring into the glycine site, possibly enabling a hydrogen bonding interaction with His27 in the T. gondii enzyme (Figure 3). The presence of a proline residue (Pro26) in DHFR, provides a favorable H-bond with a pyrimidine N, whereas this would not be feasible in the human enzyme. In addition, there could be an unfavorable interaction in the hDHFR between the pyrimidine nitrogen atoms of 3 and Pro 26. This interaction might help explain why 3-pyridine 23 is less selective than pyrimidine 3, as the pyridine N could rotate away from the proposed unfavorable interaction with Pro26 in the human enzyme. We hypothesize these are the likely reasons for the observed TgDHFR selectivity. However, it is also noted that N64 in hDHFR blocks π–π interactions. Interactions at these residues are well supported by the literature and may also contribute to the observed TgDHFR selectivity.36 A search of UniProt shows that there are no reported human poly-

potency of 3 was highly similar across these different lineages, with only 2- to 4-fold differences being observed in potency. The FLUC lines used here also carry a pyrimethamine resistance allele of DHFR that was used to generate the transgenic lines. This resistant DHFR allele confers highly level resistance to pyrimethamine as described previously, but interestingly this did not lead to cross-resistance to 3.

**Mouse Pharmacokinetic and Brain to Plasma Exposure Studies.** 2-Methoxypyrimidine 3 was selected over 2-methylpyrimidine 29 and unsubstituted pyrimidine 26 for further in vivo characterization owing to its substantially improved stability in mouse liver microsomes (MLMs). Preclinical models of toxoplasmosis are primarily performed in mice, and therefore a compound with sufficient oral bioavailability and plasma and CNS exposure to support murine efficacy testing was desired. Fortunately, 3 had moderate mouse liver microsome (MLM) intrinsic clearance (Clint) of 56.3 mL min⁻¹ kg⁻¹, which is 63% of mouse liver blood flow (LBF), whereas 29 and 26 both had high predicted clearance with MLM Clint values of 431 and 2700 mL min⁻¹ kg⁻¹, respectively, multiples above mouse LBF. The oral and iv PK parameters in mouse are summarized in Table 8. Compound 3 has low to moderate clearance of 10.6 mL min⁻¹ kg⁻¹, a volume of distribution of 1.14 L/kg, and a half-life of 3.9 h after a 1.0 mg/kg, iv dose. Oral bioavailability after a 0.83 mg/kg po dose was 47.3% with a Cmax of 178 ng/mL 30 min after dosing. The unbound fraction (%) in mouse plasma is 8.7 ± 0.2 and in brain homogenate 2.4 ± 0.3, determined using an equilibrium dialysis method. Compound 3 was freely permeable into the mouse CNS at 0.5 h after a 10 mg/kg oral dose; the concentration in brain was 2560 ± 240 ng/g and in blood 1610 ± 580 ng/mL, giving a brain to blood ratio of 1.7 ± 0.6.

**In Vivo Efficacy of 1 and 3 in a Murine Model of Acute Toxoplasmosis.** Compounds 1 and 3 were tested independently in a murine model of acute toxoplasmosis and observed to improve survival in a dose-dependent manner (Figure 6a and Figure 6b). Female CD-1 mice were inoculated intraperitoneally (ip) with 3000 tachyzoites of the highly virulent RH strain of *T. gondii* on day 0. In parallel, three negative control mice were inoculated with vehicle, lacking the parasite. The parasite strain used in this study was genetically modified to constitutively express the enzyme luciferase and enable infection monitoring via an in vivo imaging system (IVIS). Mice were monitored for survival for 30 days with intermittent IVIS monitoring (data not shown). On day 4 of dosing, compound exposure was assessed by microsampling from tail vein from three mice per group at 1, 4, and 12 h postdose and three mice per group at 2, 8, and 24 h postdose (data shown in Figure 7a and Figure 7b).

Compound 3 at doses of 10 mg/kg, q.d. or b.i.d. for 7 days, yielded 100% survival for 30 days (end of study), while doses of 1 and 3 mg/kg produced similar results on survival as comparator compound 1 did at 18 mg/kg b.i.d. and 54 mg/kg q.d., respectively. Survival data for 1 in this study were consistent with published literature. All mice treated with vehicle died within 6–7 days. It should be noted that the single animals that were lost in the 3 mg/kg compound 3 group and 54 mg/kg compound 1 group were believed to be due to handling errors during imaging rather than active *T. gondii* infection as no signs of infection or bioluminescence (data not shown) were observed for these animals during the study. Consistent with the improved in vitro potency of 3 relative to 1, it was also more potent in vivo producing similar efficacy at doses about 18-fold lower.

Cure rates were assessed by subinfection of naive mice with combined homogenized brain and lung tissue from mice that survived 30 days. The tissues from two surviving mice of the
Infection with a single *T. gondii* parasite of the type I RH strain is believed to be 100% lethal in naive mice; therefore, subinoculated naive mice that survived for 15 days and were without signs of infection was indicative of a cure (i.e., the donor mice were devoid of parasite). It should be noted that the RH strain of *T. gondii* does not typically form tissue cysts. Therefore, a cure in this model may not translate to a cure with clinically relevant strains that form tissue cysts. Nonetheless, it is clear both 1 and 3 are strongly efficacious in eradicating the tissue damaging and life threatening tachyzoite form of the parasite.

Compound 3 had a cure rate of 50% in the 1 and 3 mg/kg groups and 100% in the 10 mg/kg groups. Pyrimethamine 1 was 100% curative at the 54 mg/kg dose and 33–67% curative at the 18 mg/kg b.i.d. dose. These data suggest that inhibition of TgDHFR is sufficient for maximal efficacy as a stand-alone therapy (e.g., without coadministration of a DHPS inhibitor).

**Figure 6.** (a) Kaplan–Meier survival curves of compound 1 in CD-1 female mice ($n = 12$ for drug treated groups, $n = 9$ for vehicle group) infected with 3000 RH type 1 *T. gondii* tachyzoites on day 0 followed by oral administration of 1 beginning on day 1 through day 7. Mice were carefully monitored for signs of infection, including by intermittent imaging (data not shown). (b) Kaplan–Meier survival curves of compound 3 in CD-1 female mice ($n = 12$ for drug treated groups, $n = 9$ for vehicle group) infected with 3000 RH type 1 *T. gondii* tachyzoites on day 0 followed by oral administration of 3 beginning on day 1 through day 7. Mice were carefully monitored for signs of infection, including by intermittent imaging (data not shown).
Regarding the results for pyrimethamine 1, the human equivalent dose of 54 mg/kg in mouse (approximately 300 mg/day in a 70 kg individual) cannot be administered in patients owing to dose-limiting, mechanism-based safety issues. For both compounds, the onset of effect on survival time occurred at exposures near or slightly above the T. gondii cell-based EC$_{50}$ values (1.0 mg/kg for 3 and 18 mg/kg for 1), with maximal effects occurring at dose levels of 3 mg/kg and 10 mg/kg for 3 and 54 mg/kg for 1 (Figure 7a and Figure 7b), which exceed the cell-based EC$_{50}$ values.

### CONCLUSIONS

Rational drug design led to the identification of several highly selective and potent arylpiperazine-based TgDHFR inhibitors. The structure–activity relationship for these compounds provides proof-of-concept for the feasibility of discovering a next generation toxoplasmosis treatment with improved potency, selectivity, and safety. 2-Methoxyprymidine 3, with 16-fold better selectivity for TgDHFR and 89-fold better potency as compared to pyrimethamine 1 and with desirable DMPK and safety properties, was selected for exploration in preclinical models of toxoplasmosis. Compound 3 was effective in radical cure of acute infection with the highly virulent type I RH strain in the murine model and showed similar potency across multiple parasite lineages in cell-based parasite growth assays. On the basis of the efficacy observed, we hypothesize it will be feasible to achieve parasitcidal levels of 3 in patients that are below concentrations that would inhibit hDHFR, thus providing a safer and more efficacious therapy than is currently available and possibly obviating the need for sulfonamide combination therapy.

### EXPERIMENTAL SECTION

**Materials and Methods. General.** All synthetic chemistry, DMPK, T. gondii DHFR crystal structures with 3 and 29, and DHFR in vitro pharmacology were performed at WuXi AppTec at the China facilities in Tianjin and Shanghai. Work with Toxoplasma gondii was performed at Evotec in Manchester, U.K., and in Prof. Sibley’s lab at Washington University, St. Louis, MO. Protein NMR spectra were recorded on a Varian 400 MHz NMR. LC/MS data were taken on a quadrapole mass spectrometer on Shimadzu LC/MS 2010 column (Separ ODS 50 mm x 2.0 mm, 5 μm) or Agilent 1200 HPLC, 1956 MSD (column Shim-pack XR-ODS 30 mm x 3.0 mm, 2.2 μm) operating in ES (+) ionization mode. All final compounds were greater than 95% pure based on HPLC UV% AUC. Structures were determined by $^1$H NMR and LC/MS. Final compounds in this manuscript are not known to interfere with the assays herein (i.e., they are not PAINS).

All animal studies were conducted at WuXi AppTec in China and Evotec in Manchester, U.K., and were performed in accordance with the institutional guidelines for these countries and laboratories.

**LC/MS methods.**

**Method A.** Method A was run on a Shimadzu LC-20AB with a MS 2010 detector using a Luna-C18 (1 column (2.0 mm x 30 mm, 3 μm) at 40 °C. Mobile phase A was 10 mM aqueous NH$_4$HCO$_3$ and mobile phase B was acetonitrile. The flow rate was 0.8 mL/min from 0.01 to 1.51 min, then 1.2 mL/min from 1.52 to 2.00 min. The gradient ran from 90% mobile phase A to 10% mobile phase A over 1.15 min, then remained at 10% mobile phase A through 1.65 min, then back to 90% mobile phase A at 1.66 min and was maintained at 90% mobile phase A for 2.0 min. The UV detection was 220 nm, and the MS was measured in positive ion mode.

**Method B.** Method B was run on an Agilent 1200 with a MS 6120 detector using an Xbridge Shield RP18 column (2.1 mm x 50 mm, 5 μm) at 40 °C. Mobile phase A was 10 mM aqueous NH$_4$HCO$_3$ and mobile phase B was acetonitrile. The flow rate was 1.0 mL/min from 0.01 to 2.48 min, then 1.2 mL/min from 2.50 to 3.00 min. The gradient ran from 90% mobile phase A to 20% mobile phase A over 2.00 min, then remained at 20% mobile phase A through 2.48 min, then back to 90% mobile phase A at 2.50 min and maintained at 90% mobile phase A through 3.0 min. The UV detection was 220 nm, and the MS was measured in positive ion mode.

**Method C.** Method C was run on an Agilent 1200 with a MS 6120 detector using an Xbridge Shield RP18 column (2.1 mm x 50 mm, 5 μm) at 40 °C. Mobile phase A was 10 mM aqueous NH$_4$HCO$_3$ and mobile phase B was acetonitrile. The flow rate was 1.0 mL/min from 0.01 to 2.50 min, then 1.2 mL/min from 2.51 to 3.00 min. The gradient ran from 90% mobile phase A to 10% mobile phase A over 1.50 min, then remained at 10% mobile phase A through 2.50 min and then back to 70% mobile phase A at 2.51 min and maintained at 70% mobile phase A through 3.0 min. The UV detection was 220 nm, and the MS was measured in positive ion mode.

**Chemistry.**

The compounds in Figure 2 were sourced as follows. Compound 2 was prepared as described previously. Pyrimethamine (1) was sourced from the drug manufacturer, and $^1$H NMR and LC/MS data confirmed structure and purity of 99.9%. Trimethoprim (4) was purchased from a commercial supplier as the lactate salt, and $^1$H NMR and LC/MS data confirmed structure with a purity of 98.7%. Methotrexate (5) was purchased from a commercial supplier, and $^1$H NMR and LC/MS data confirmed structure with a purity near 100%. Trimetrexate (6) was purchased from a commercial supplier as the

![Figure 7.](image-url)
yield) used as such in the next step. LC/MS method B (ESI+): purity 97.8%.

Step 1. 5-(4-(3-Bromophenyl)piperazin-1-yl)pyrimidine-2,4-dione (37n). To a mixture of 5-bromo-1H-pyrimidine-2,4-dione 33 (7.92 g, 42 mmol, 1.0 equiv) and 1-(3-bromophenyl)piperazine 36n (10.0 g, 42 mmol, 1.0 equiv) in DMSO (200 mL) was added potassium fluoride (5.0 g, 94 mmol, 2.0 equiv). The resulting mixture was stirred at 130 °C for 12 h, cooled to room temperature, and poured into 300 mL of water. The precipitate was collected by suction filtration, washed with 200 mL of EtOH, and dried in vacuo leaving 5-(4-(3-bromophenyl)piperazin-1-yl)pyrimidine-2,4-dione 37n as a brown solid (10.6 g, 30.2 mmol, 73.5% yield) used as such in the next step. LC/MS method B (ESI+): expected m/z 351 (M + 1)+; found m/z 351 (M + 1)+; DIPEA (14.4 g, 111 mmol, 3.9 equiv) in 70 mL of toluene was cooled to 10 °C, and POCl₃ (15.8 g, 103 mmol) was added over 1 h, keeping the reaction temperature 20 °C. The mixture was stirred at 20 °C for 1 h, heated to 95 °C, and held at 95 °C for 12 h. LC/MS was consistent with the desired product MS. The reaction mixture was concentrated under reduced pressure to give a black residue, which was diluted with cold water (200 mL) and extracted with DCM (3×). The combined organic layers were washed with brine (2×), diluted with cold water (200 mL), and extracted with DCM (3×). The combined layers were washed with water (2×), and concentrated under reduced pressure to give a yellow solid. 1H NMR (DMSO-d₆, 400 MHz) δ = 7.54 (m, 5H), 7.39 (m, 1H), 7.24 (br d, J = 7.6 Hz, 2H), 7.21 (br d, J = 7.2 Hz, 2H), 7.12−7.05 (m, 2H), 5.99 (br s, 1H), 5.60 (s, 2H), 2.88 (br s, 4H), 2.64 (br s, 4H). LC/MS (M + 1) expected MW 347.2, observed MW 347.2, UV purity 97.8%.

5-(4-(1,1′-Biphenyl)-2-yl)piperazin-1-yl)pyrimidine-2,4-dione (36g) to give 1 in 10.6% yield as a white solid. 1H NMR (methanol-d₄) δ = 7.60−7.50 (m, 5H), 7.39 (br t, J = 7.4 Hz, 2H), 7.30−7.23 (m, 1H), 7.10 (br d, J = 8.6 Hz, 2H), 3.48−3.36 (m, 4H), 3.03 (br d, J = 4.3 Hz, 4H). LC/MS (M + 1) expected MW 347.2, observed MW 347.2, UV purity 96.7%.

5-(4-(O-Toly)piperazin-1-yl)pyrimidine-2,4-diamine (10). 10 was prepared in an analogous 3 step manner as described for 32 starting with 1-(4-toly)piperazine (36e) to give 10 in 32.8% yield as a white solid. 1H NMR (methanol-d₄) δ = 7.53 (s, 1H), 7.21−7.11 (m, 3H), 7.03−6.97 (m, 1H), 3.10 (br s, 4H), 3.03 (br d, J = 4.0 Hz, 4H), 2.34 (s, 3H). LC/MS (M + 1) expected MW 285.2, observed MW 285.2, UV purity 99.4%.

5-(4-(M-Toly)piperazin-1-yl)pyrimidine-2,4-diamine (11). 11 was prepared in an analogous 3 step manner as described for 32 starting with 1-(4-toly)piperazine (36f) to give 11 in 7.2% yield as a yellow solid. 1H NMR (DMSO-d₆) δ = 7.59 (s, 1H), 7.10 (t, J = 7.8 Hz, 1H), 6.83−6.70 (m, 2H), 6.60 (br d, J = 7.4 Hz, 1H), 6.08 (br s, 2H), 5.62 (s, 2H), 3.23 (br s, 4H), 2.86 (br t, J = 4.3 Hz, 4H), 2.25 (s, 3H). LC/MS (M + 1) expected MW 285.1, observed MW 285.1, UV purity 99.5%.

5-(4-(P-Toly)piperazin-1-yl)pyrimidine-2,4-diamine (12). 12 was prepared in an analogous 3 step manner as described for 32 starting with 1-(4-toly)piperazine (36g) to give 12 in 2.3% yield as a white solid. 1H NMR (DMSO-d₆) δ = 7.58 (s, 1H), 7.03 (d, J = 8.4 Hz, 2H), 6.86 (d, J = 8.4 Hz, 2H), 6.06 (br s, 1H), 5.60 (s, 2H), 3.19 (br s, 4H), 2.87 (d, J = 4.0 Hz, 4H). LC/MS (M + 1) expected MW 285.1, observed MW 285.1, UV purity 98.1%.

5-(4-(2-Chlorophenyl)piperazin-1-yl)pyrimidine-2,4-diamine (13). 13 was prepared in an analogous 3 step manner as described for 32 starting with 1-(2-chlorophenyl)piperazine (36h) to give 13 in 19.4% yield as a light yellow solid. 1H NMR (DMSO-d₆) δ = 7.62 (s, 1H), 7.42 (br d, J = 7.8 Hz, 1H), 7.35−7.28 (m, 1H), 7.18 (br d, J = 7.8 Hz, 1H), 7.05 (br t, J = 7.4 Hz, 1H), 6.09 (br s, 2H), 5.65 (2H), 3.11 (br s, 4H), 2.91 (br d, J = 3.9 Hz, 4H). LC/MS (M + 1) expected MW 305.1, observed MW 305.1, UV purity 99.1%.

5-(4-(3-Chlorophenyl)piperazin-1-yl)pyrimidine-2,4-diamine (14). 14 was prepared in an analogous 3 step manner as described for 32 starting with 1-(3-chlorophenyl)piperazine (36i) to give 14 in 24.2% yield as a white solid. 1H NMR (DMSO-d₆) δ = 7.16 (br s, 1H), 8.43 (br s, 1H), 7.65 (br s, 1H), 7.56 (br s, 1H), 7.43 (br s, 2H), 7.23 (br t, J = 8.4 Hz, 1H), 6.98 (br s, 1H), 6.93 (br d, J = 8.4 Hz, 1H), 6.80 (br d, J = 7.6 Hz, 1H), 3.36 (br s, 4H), 2.86 (br s, 4H). LC/MS (M + 1) expected MW 305.1, observed MW 305.1, UV purity 99.1%.
5-(4-(3-(Trifluoromethoxy)phenyl)piperazin-1-yl)-pyrimidine-2,4-diamine (18). 18 was prepared in an analogous 3 step manner as described for 32 starting with 1-(3-trifluoromethoxyphenyl)piperazine (36m) to give 18 in 22.7% yield as a yellow solid. 1H NMR (methanol-d4) δ = 7.49 (s, 1H), 7.31 (t, J = 8.2 Hz, 1H), 6.98 (d, J = 7.9 Hz, 1H), 6.84 (s, 1H), 6.72 (d, J = 7.9 Hz, 1H), 3.38 (s, 4H), 2.99 (s, 4H). LC/MS (M + 1) expected MW 355.1, observed MW 355.1, UV purity 100%.

5-(4-[[1,1′-Biphenyl]-3-yl)piperazin-1-yl]-6-methylpyrimidine-2,4-diamine (20). 20 was prepared in an analogous 3 step manner as described for 32 starting with 1-(1,1′-biphenyl)-3-yl)piperazine (36a) and 5-bromo-6-ethyluracil (35) to give 20 in 31.8% yield as a yellow solid. 1H NMR (methanol-d4) δ = 7.64–7.57 (m, 2H), 7.51–7.28 (m, 4H), 7.20 (br d, J = 7.5 Hz, 1H), 7.09 (br d, J = 7.9 Hz, 1H), 3.66 (br d, J = 11.5 Hz, 2H), 3.45–3.35 (m, 2H), 3.26–3.16 (m, 2H), 3.03 (br d, J = 11.5 Hz, 2H), 2.38 (s, 3H). LC/MS (M + 1) expected MW 361.2, observed MW 361.1, UV purity 95.9%

5-(4-[[1,1′-Biphenyl]-3-yl)piperazin-1-yl]-6-ethylpyrimidine-2,4-diamine (21). 21 was prepared in an analogous 3 step manner as described for 32 starting with 1-(1,1′-biphenyl)-3-yl)piperazine (36a) and 5-bromo-6-ethyluracil (35) to give 21 in 71.4% yield as a white solid. 1H NMR (methanol-d4) δ = 7.61 (d, J = 7.2 Hz, 2H), 7.43 (d, J = 8.0 Hz, 4H), 7.36 (d, J = 6.4 Hz, 1H), 7.30 (d, J = 7.2 Hz, 1H), 7.18 (d, J = 7.2 Hz, 1H), 3.65 (d, J = 9.2 Hz, 2H), 3.44–3.31 (m, 4H), 3.12 (d, J = 8.8 Hz, 2H), 2.73 (d, J = 7.6 Hz, 2H), 1.33 (t, J = 6.8 Hz, 3H). LC/MS (M + 1) expected MW 375.2, observed MW 375.1, UV purity 98.7%.

Compounds 3, 19, 23, 24, 26, 28, 30, and 31 were prepared in a similar fashion as described below for the synthesis of 29.

5-(4-(3-((2-Methylpyrimidin-5-yl)phenyl)piperazin-1-yl)-pyrimidine-2,4-diamine (29). A mixture of S-(4-(3-bromophenyl)piperazin-1-yl)pyrimidine-2,4-diamine 32 (1.0 g, 2.8 mmol, 1.0 equiv), (2-methylpyrimidin-5-yl)boronic acid (m, 4H), 3.12 (d, J = 7.2 Hz, 1H), 7.36 (d, J = 6.4 Hz, 1H), 7.20 (br d, J = 7.5 Hz, 1H), 7.09 (br d, J = 7.9 Hz, 1H), 3.66 (br d, J = 11.5 Hz, 2H), 3.45–3.35 (m, 2H), 3.26–3.16 (m, 2H), 3.03 (br d, J = 11.5 Hz, 2H), 2.38 (s, 3H). LC/MS (M + 1) expected MW 361.2, observed MW 361.1, UV purity 95.9%

5-(4-[[1,1′-Biphenyl]-3-yl)piperazin-1-yl]-6-ethylpyrimidine-2,4-diamine (21). 21 was prepared in an analogous 3 step manner as described for 32 starting with 1-(1,1′-biphenyl)-3-yl)piperazine (36a) and 5-bromo-6-ethyluracil (35) to give 21 in 71.4% yield as a white solid. 1H NMR (methanol-d4) δ = 7.61 (d, J = 7.2 Hz, 2H), 7.43 (d, J = 8.0 Hz, 4H), 7.36 (d, J = 6.4 Hz, 1H), 7.30 (d, J = 7.2 Hz, 1H), 7.18 (d, J = 7.2 Hz, 1H), 3.65 (d, J = 9.2 Hz, 2H), 3.44–3.31 (m, 4H), 3.12 (d, J = 8.8 Hz, 2H), 2.73 (d, J = 7.6 Hz, 2H), 1.33 (t, J = 6.8 Hz, 3H). LC/MS (M + 1) expected MW 375.2, observed MW 375.1, UV purity 98.7%.

Compounds 3, 19, 23, 24, 26, 28, 30, and 31 were prepared in a similar fashion as described below for the synthesis of 29.

5-(4-(3-((2-Methylpyrimidin-5-yl)phenyl)piperazin-1-yl)-pyrimidine-2,4-diamine (29). A mixture of S-(4-(3-bromophenyl)piperazin-1-yl)pyrimidine-2,4-diamine 32 (1.0 g, 2.8 mmol, 1.0 equiv), (2-methylpyrimidin-5-yl)boronic acid (39u) (395 mg, 2.2 mmol, 1.0 equiv), Cs2CO3 (1.4 g, 4.3 mmol, 1.5 equiv), Pd(PPh3)4 (0.65 g, 0.7 mmol, 2.2 equiv), (2-methylpyrimidin-5-yl)boronic acid (m, 4H), 3.12 (d, J = 7.2 Hz, 1H), 7.36 (d, J = 6.4 Hz, 1H), 7.20 (br d, J = 7.5 Hz, 1H), 7.09 (br d, J = 7.9 Hz, 1H), 3.66 (br d, J = 11.5 Hz, 2H), 3.45–3.35 (m, 2H), 3.26–3.16 (m, 2H), 3.03 (br d, J = 11.5 Hz, 2H), 2.38 (s, 3H). LC/MS (M + 1) expected MW 361.2, observed MW 361.1, UV purity 95.9%
for 22 starting with 32 and tributyl[(pyrazin-2-yl)stannane (40z) to give 27 in 50.1% yield as a light yellow solid. 31H NMR (methanol-d$_4$) δ = 9.19 (s, 1H), 8.73 (s, 1H), 8.60 (br d, J = 2.0 Hz, 1H), 8.30 (s, 1H), 8.11 (br d, J = 7.6 Hz, 1H), 7.73–7.65 (m, 2H), 7.62 (s, 1H), 3.85 (br s, 4H), 3.30–3.26 (m, 4H). Expected MW 349.2, observed MW 349.2, UV purity 99.1%.

**DHFR Assay for Human and** T. gondii All compounds were tested in duplicate and replicated in at least 3 independent experiments. Human and T. gondii DHFR assays were run in parallel using the same stocks to optimize selectivity data. Key comparator compounds 1 (n = 12 for human and T. gondii) and 3 (n = 16 for human and T. gondii) were tested in free base form on the same days for optimal comparison. The protein expression and purification protocol were adapted from a previously published procedure. 29 T. gondii TS-DHFR was subcloned into a PET15b plasmid and transformed into Escherichia coli BL21 competent cells. Overcultured bacteria were inoculated into a 1 L of LB culture media at a concentration of 0.02–0.1 OD at 600 nm. The plates were centrifuged at 300 × g, and the supernatant (25 mL, Sigma R7017). After incubation at 37 °C for 16 h, cells were pelleted (~4.6 g) and resuspended in buffer A (25 mM Triis-HCl, pH 7.3, 100 mM NaCl, 1 mM EDTA) before lysis by sonication. MTX agarose beads (150 mM KCl, 8.9 mM Na$_2$EDTA) prior to elution with buffer B (~10 mL, 25 mM Triis-HCl, pH 7.3, 1 M KCl, 1 mM EDTA) prior to elution with buffer C (~6 mL, 25 mM Triis-HCl, 10 mM DTT, 10% glycerol, 2 mM H$_2$F). The eluent containing the purified enzyme was then concentrated and the protein was transferred, using a PD-MiniTrap G-25 column, to the final storage buffer (25 mM Triis-HCl, 10 mM DTT, 10% glycerol). Purified hDHFR was obtained commercially from Sigma-Aldrich, dihydrofolate reductase human (Sigma D6566). The protein was confirmed by sequencing.

The diaphorase-coupled assay for DHFR activity was adapted from a previously published procedure. 33 Compounds were added as solutions of DMSO at 100X the desired concentration to purified enzyme (1 μg/mL) suspended in assay buffer (150 mM KCl, 8.9 mM β-mercaptoethanol in 40.0 mM sodium phosphate at pH 7.4) in 384-well format (Corning 3573). Following a 15 min incubation at 25 °C, solutions of NADPH (1.6 μM, Sigma N7505) and DHF (10 μM, Sigma D7006) in assay buffer were added sequentially. The plate was then incubated at 25 °C for an additional 60 min prior to the addition of diaphorase (10 U/mL) and resazurin (5 μM, Sigma R7017). After a final 10 min incubation at 25 °C, fluorescence was measured using an EnVision plate reader (331 nm Ex/590 nm Em). IC$_{50}$ values were determined from the raw fluorometric data by nonlinear regression using GraphPad Prism.

**Parasite Strains and Cell Lines.** Tachyzoites of T. gondii strains were grown in monolayers of human foreskin fibroblasts (HFF) (ATCC SCRC 1041) maintained in complete medium (DMEM containing 10% FBS, 2 mM t-glutamine, 10 mM HEPES, and 10 μg/mL gentamicin in 35 mM NaHCO$_3$ solution), 37 °C in 5% CO$_2$. Following natural egress, tachyzoites were purified in HBSS containing 10 mM HEPES, 0.1 mM EDTA and separated from host debris using 3.0 micro polycarbonate membrane filters, followed by centrifugation at 400g.

**Cell-Based Parasite Growth Assays Using β-Galactosidase.** This work was performed at Evotec in Manchester, U.K. Parasite growth inhibition assays were conducted using the type 1 RH strain, 2F clone that expresses bacterial β-galactosidase (β-gal), as described previously. 35 Compounds dissolved in DMSO at 10 mM stocks were diluted in medium to 2 times final concentrations and added to an equal volume of medium containing 5 × 10$^5$ parasites and incubated for 20 min. Mixtures of compounds (ranging from 10 μM to 0.01 nM) containing 0.1% (v/v) DMSO or DMSO alone was added to monolayers of HFF cells grown in 96-well plates, centrifuged at 300g for 5 min, and returned to culture at 37 °C, 5% CO$_2$. The cells were preincubated for 2 h in the presence of parasites. Varying concentrations of drugs were added to each well (100 μL volumes containing 0.2% DMSO in D10 media) to give a final concentration range of 0.02–10 μM in 0.1% DMSO. The plates were centrifuged at 300g for 5 min at room temperature and then incubated at 37 °C in 5% CO$_2$ for 72 h. At the end of the incubation period, the monolayer was lysed in 1% Triton X-100 and β-gal activity monitored using 1 mM chlorophenol red β-galactopyranoside by absorption at 570 nm, as described previously. 35 Individual EC$_{50}$ values were determined from three or more independent biological replicates and are reported as mean values.

**Generation of Firefly Luciferase (FLUC) Tagged Strains.** This work was performed at Washington University in St. Louis, MO. Experiments were conducted with the ME49Δhcr:FLUC strain of T. gondii, a transgenic line that expresses firefly luciferase (FLUC). 37 To tag additional strains with FLUC, a reporter plasmid was generated using a two-step Gibson assembly approach. Fragment 1 was generated from PCR linearized pUPRT-Flxed DHFR-TS$^+$ plasmid (Addgene no. 100060) that includes both 5' and 3' uracil phosphoribosyltransferase (UPRT) flanking regions to drive locus specific integration at the UPRT gene and a flxed T. gondii DHFR selectable marker. Fragment 2 was synthesized using a gBlock (IDT DNA) containing the constitutive T. gondii α-tubulin promoter (608-bp) driving expression of the firefly luciferase reporter (1641-bp). The expression construct was targeted to the UPRT gene in T. gondii by co-transfection with the CRISPR plasmid pSAG1:αCAS9, U6:gupURP. Parasites were sequentially selected in pyrimethamine (1.0 μM) followed by 5-fluorodeoxyuracil (FUDR, 10 μM) and independent clones isolated by limiting dilution. All clones contain the flxed T. gondii DHFR selectable marker that can be excised using a耙ing CRE recombine.

**In Vitro Growth Assays Using Luciferase.** To assess potency of compounds on different strains of T. gondii, values were determined from a 10-point dose—response curve. Briefly, 5 × 10$^5$ of luciferase expressing parasites (100 μL/well) were added to a 96-well plate that contained 100 μL of 2X compound concentration (to achieve 1X final compound concentration in 200 μL total well volume containing 0.1% DMSO) and allowed to replicate for 72 h prior to preparation for luciferase assay. All experimental steps, growth conditions, and luciferase assay protocols were completed as described above. Compounds were tested using a 3-fold dilution series from 10 μM to 0.001 μM with all wells containing a final concentration of 0.1% DMSO. The EC$_{50}$ data are presented as the average of three or more biological replicates (i.e., separate EC$_{50}$ triturations) each with two technical replicates (i.e., separate wells).

**Antiproliferative Assay in MCF7 Cells.** This work was performed at Cyprex in Watertown, MA. MCF-7 cells were plated on 96-well tissue culture treated polystyrene plates at 0.75 × 10$^5$ cells in 100 μL of MEM/EBSS (supplemented with 10% fetal bovine serum, sodium pyruvate, and antibiotics) per well. After an overnight incubation at 37 °C, the cells were dosed with test compounds and controls at a range of concentrations and incubated for 72 h at 37 °C. Pyrimethamine 1 was tested from 0.156 to 20 μM, and compound 3 was evaluated from 0.313 to 40 μM with an 8-point dose curve in triplicate on three separate plates. Cell viability was measured using the Promega CellTiter 96 nonradioactive cell proliferation assay (MTT) kit by adding 15 μL of the dye solution to each well and incubating for 3 h at 37 °C. After incubation, 100 μL of the solubilization solution/stop mix was added to each well. Plates were incubated at 37 °C for 1 h, mixed on a plate shaker for 10 min, and then absorbance was read at 570 nm. The EC$_{50}$ was then calculated.

**Pharmacokinetics (Mouse).** Fasted female CD-1 mice (n = 3), 6–8 weeks old (supplied from Beijing Vital River Laboratory Animal Technology Co., Ltd.) were administered a 0.5 mg/kg intravenous dose of compound 3, formulated as a clear 0.1 mg/mL solution in saline at pH 5. A second group (n = 3) was administered a 0.83 mg/kg oral dose of compound 3 (targeted dose was 1.0 mg/kg), formulated as a 0.1 mg/mL homogeneous opaque suspension with fine particles in 0.5% CMC. Plasma (EDTA-K$_3$) from the iv dose was collected at 0.083, 0.50, 1.0, 2.0, 4.0, 8.0, and 24 h. Plasma (EDTA-K$_3$) from the po dose was collected at 0.50, 1.0, 2.0, 4.0, 8.0, 12, and 24 h. Plasma preparation: An aliquot of 10 μL plasma was protein precipitated with 100 μL of IS, and the mixture was vortexed and centrifuged at 13 000 rpm for 10 min, 4 °C. The supernatant (25 μL)
was then mixed with 25 μL of water/ACN (v:v, 95:5) containing 0.1% formic acid, vortexted, and centrifuged at 4 °C. 3 μL of supernatant was injected for LC−MS/MS analysis. Concentration of compound 3 was determined using an LC−MS/MS-AG (API 4000) instrument in ESI positive mode with SRM detection monitoring for [M + H]+ m/z transition 379.3/152.2 and using an internal standard 100 ng/mL tolbutamide [M + H]+ m/z transition 271.1/155.1. The UPLC method mobile phase A of 0.025% formic acid, 1 mM NH4OAc in water/ACN (v:v, 95:5) and mobile phase B of 0.025% formic acid, 1 mM NH4OAc in ACN/water (v:v, 95:5) used a gradient starting with 15% mobile phase B and going to 90% over 1.40 min, on an Acquity UPLC BEH C18 1.7 μm, 2.1 mm × 50 mm column at 60 °C at a flow rate of 0.7 mL/min. The retention time of compound 3 was 0.55 min and tolbutamide 0.88 min. A calibration curve from 1.00 to 3000 ng/mL of compound 3 in male CD-1 mouse plasma (EDTA-K2) was made, and the data were analyzed using Phoenix WinNonlin 6.3 with a linear/log trapezoidal calculation method.

Brain to Blood Ratio (Mouse). This work was performed at Evotec, Manchester, U.K. Fed female CD1 mice (n = 3) were orally administered 10 mg/kg of the TFA-salt form of compound 3, formulated as a clear solution in 0.25% carboxymethyl cellulose (CMC). Blood (EDTA-K2) 20 μL was collected by tail prick of the lateral tail vein 0.5 h postdose and diluted 2× with water for LC−MS/MS injection. Animals were then euthanized, and brain was collected and homogenized. The brain homogenates (40 μL) were run within the blood calibration curve and utilized the homogenization dilution factors for final quantitation but also incorporated a 2-fold adjustment for sample volume versus blood.

In Vivo Murine Model of Toxoplasmosis. This work was performed at Evotec in Manchester, U.K. Fed female CD1 mice (60 mice per study; 12 mice per drug treatment group, 9 mice for vehicle and 3 mice as negative controls) were inoculated intraepithelionally with 3000 tachyzoites of the highly virulent RH strain of T. gondii on day 0. The T. gondii strain used in this study had been genetically modified to constitutively express the enzyme fire fly luciferase (FLUC) and enable infection monitoring via an in vivo bioluminescence imaging system.51 Beginning 24 h after inoculation, mice were dosed with either compound 1 formulated at 0.6, 1.8, and 5.4 mg/mL in 0.25% CMC or the TFA salt form of compound 3 formulated in 0.25% CMC at 0.1 mg/mL, 0.3 mg/mL, or 1.0 mg/mL as a clear solution and dosed at a volume of 10 μL/kg. On day 4 microsampling of blood from the tail vein was collected into K2EDTA tubes and evaluated by LC−MS−MS as described above for the mouse brain to blood experiment.
